ABSTRACT

Introduction
Patients with transient ischaemic attack (TIA) or stroke are at risk for cognitive impairment and dementia. Currently, there is no known effective strategy to prevent this cognitive decline. Increasing evidence exists that physical exercise is beneficial for cognitive function. However, in patients with TIA or stroke who are at risk of cognitive impairment and dementia, only a few trials have been conducted. In this study, we aim to investigate whether a physical exercise programme (MoveIT) can prevent cognitive decline in patients in the acute phase after a TIA or minor ischaemic stroke.

Methods and analysis
A single-blinded randomised controlled trial will be conducted to investigate the effect of an aerobic exercise programme on cognition compared with usual care. 120 adult patients with a TIA or minor ischaemic stroke less than 1 month ago will be randomly allocated to an exercise programme consisting of a 12-week aerobic exercise programme and regular follow-up visits to a specialised physiotherapist during the period of 1 year or to usual care. Outcome measures will be assessed at the baseline, and at the 1-year and 2-year follow-up. The primary outcome is cognitive functioning measured with the Montreal Cognitive Assessment (MoCA) test and with additional neuropsychological tests. Secondary outcomes include maximal exercise capacity, self-reported physical activity and measures of secondary prevention.

Ethics and dissemination
The study received ethical approval from the VU University Amsterdam Ethics committee (2011/383). The results of this study will be published in peer-reviewed journals and presented at international conferences. We will also disseminate the main results to our participants in a letter.

Trial registration number
The Nederlands Trial Register NTR3884.
Introduction

Patients with transient ischaemic attack (TIA) or ischaemic stroke have an increased risk of developing cognitive impairment and dementia.\textsuperscript{1,2} Cognitive impairment not only occurs in patients with major stroke, but also in patients after TIA or minor stroke.\textsuperscript{3-5} In a meta-analysis of 7511 patients, 10% developed new dementia after the first stroke and more than a third had dementia after a recurrent stroke.\textsuperscript{1} In patients with stroke, the prevalence of mild cognitive impairment varies between 20% and 90%.\textsuperscript{2,6} In addition, multiple studies demonstrated that the occurrence of cognitive impairment or dementia after stroke predicts death and dependency.\textsuperscript{7-10} Currently, there is no known effective strategy to prevent cognitive decline or dementia in these patients.

Physical activity has been associated with a decreased risk for dementia and cognitive decline.\textsuperscript{11,12} In healthy elderly individuals, there is evidence that a physical exercise programme is associated with an improvement in cognitive performance.\textsuperscript{13} Current stroke guidelines advise at least 30 min of moderate-intensity physical exercise 3–7 times a week for patients with TIA or ischaemic stroke who are capable of engaging in physical activity.\textsuperscript{14} For patients after myocardial infarction, a physical exercise programme is standard care and a part of cardiac rehabilitation, and this exercise programme is associated with a reduced mortality.\textsuperscript{15}

In patients with vascular diseases, conflicting results have been found with regard to the association between physical activity and cognition. One cohort study found that physical activity was associated with better preservation of cognitive function;\textsuperscript{16} another recent study could not confirm this association.\textsuperscript{17} Until now, three observational studies and only one randomised controlled trial have assessed the effect of a physical exercise programme on cognition in patients with a TIA
or stroke.\textsuperscript{18-21} This randomised controlled trial only included patients who had a stroke more than 6 months ago and found an improvement in motor learning.\textsuperscript{19} No randomised controlled trials have been performed in the acute phase following a TIA or stroke. Previously, we demonstrated the safety and feasibility of an exercise programme in the acute phase after a TIA or a minor ischaemic stroke.\textsuperscript{22} The aim of this larger study is twofold: (1) to investigate whether a physical exercise programme (MoveIT) can prevent cognitive decline in patients after a TIA or minor ischaemic stroke, and (2) to investigate the effect of this programme on cardiorespiratory fitness and the attainment of secondary prevention targets.

**Methods and analysis**

**Study design and setting**

MoveIT is a two parallel group, single-centre, single-blinded, randomised controlled trial to investigate the effects of an aerobic exercise programme on cognition in patients in the acute phase after TIA or minor ischaemic stroke (Figure 1). The study will be conducted in the Sint Lucas Andreas Hospital, a district hospital in Amsterdam with a specialised stroke unit. Participants will be randomly assigned to a control or intervention group. The control group will receive the usual care for patients after TIA or minor ischaemic stroke, consisting of two or three visits to the outpatient clinic. The intervention group will participate in the MoveIT programme, which consists of a 12-week aerobic exercise programme and follow-up visits to a specialised physiotherapist every 3 months during the period of 1 year. Study procedures were approved by local university and hospital research ethics committees. Informed written consent will be obtained from all participants. The study has been registered at the trial registration (Nederlands Trial Register—NTR3884).
**Objectives**

*Primary objective:* To investigate the effect of a physical exercise programme (MoveIT) on cognition in patients in the acute phase after a TIA or minor ischaemic stroke, compared with participation in usual care.
Secondary objectives:

- To investigate the effect of a physical exercise programme on cardiorespiratory fitness, measured by maximal exercise capacity.
- To investigate the effect of a physical exercise programme on the attainment of secondary prevention targets, defined as the combination of prescribed antithrombotic therapy (antiplatelet agents or oral anticoagulants) and achievement of blood pressure (<140/90 mm Hg) and low-density lipoprotein cholesterol (LDL-C; <100 mg/dl) targets, as recommended in international guidelines. 

Participants

Inclusion criteria

Patients are eligible if they (1) are at least 18 years old, (2) present with a TIA or minor ischaemic stroke as defined by the National Institutes of Health Stroke Scale (NIHSS) score ≤3, (3) had the onset of signs and symptoms less than 1 month ago, (4) are able to walk independently and (5) are discharged from hospital without need for further rehabilitation.

Exclusion criteria

Patients will be excluded if they have (1) dementia or a Mini-Mental State Examination (MMSE) score <24, (2) aphasia or the inability to speak Dutch, (3) cardiopulmonary contraindication for physical exercise and exercise testing outlined by the American College of Sports Medicine (ACSM) or (4) chronic disease with an expected survival of less than 2 years.

Recruitment

Consecutive patients with a TIA or a minor ischaemic stroke admitted to the stroke unit or evaluated in the outpatient clinic or emergency room of the Sint Lucas Andreas Hospital will be given information about the trial. Patients who are interested to participate will be approached with further information and screened for cardiac
contraindication using a cardiac checklist. This cardiac checklist has been developed by our study group and consists of items concerning the patient’s medical history, disease history, physical and ancillary (ECG) investigations. Before randomisation, all potential participants with a positive cardiac checklist will be examined by a cardiologist to exclude possible cardiac contraindication for maximal exercise testing or a physical exercise programme. After exclusion of cardiac contraindications or a negative cardiac checklist, written informed consent will be obtained. If there are indications of pulmonary disease, patients will be referred to a pulmonologist to optimise the pulmonary function prior to the start of the programme.

**Randomisation**
Consenting participants will be allocated for treatment using block randomisation with a block size of two. The allocation sequence will be generated by coin tossing. Randomisation will be conducted independently using sealed opaque envelopes.

**Intervention**
Participants randomly assigned to the intervention group will participate in the MoveIT programme. This programme consists of a 12-week aerobic exercise programme, combined with regular follow-up visits to a specialised physiotherapist during the period of 1 year. During the aerobic exercise programme, participants will receive two 1 hour exercise sessions per week supervised by two specialised physiotherapists. These sessions consist of aerobic exercise and strength training. The exercise intensity will be based on the individual’s maximal heart rate and the maximal power achieved during the maximal exercise test. During the programme, the exercise intensity will gradually be increased. Participants will start with home-based aerobic exercise and will gradually increase this frequency to three times a week. Participants will keep a log of these activities and will discuss their progress with the physiotherapists during the
exercise sessions and during the follow-up visits after the completion of the exercise programme.

After the completion of the physical exercise programme, follow-up consists of a total of three visits to the physiotherapist during the period of 1 year. During these appointments, participants will receive motivational interviewing-based counselling by physiotherapists in order to motivate them to maintain an active lifestyle. Participating physiotherapists received a motivational interviewing training and have considerable experience with this technique.

Control group
Participants in both groups will continue to receive usual stroke care. Usual care consists of a total of 2–3 follow-up visits to the outpatient clinic for 3 months after the TIA or stroke. During these appointments, the motivational interviewing-based counselling will be focused on the attainment of secondary prevention and the improvement of lifestyle factors and physical activity.

Data collection and outcomes measures
Outcome measures will be assessed at the baseline, and at the 1-year and 2-year follow-up by personnel blinded to the treatment allocation. Data will be recorded on standardised forms and entered into a secured Access database with Structured Query Language (SQL) that contains quality control checks (eg, range checks, notification of missing data).

Cognitive functioning
The primary endpoint is global cognitive functioning measured using the Montreal Cognitive Assessment (MoCA) test, which has been validated to measure cognitive decline in patients after stroke. In addition, a standardised neuropsychological examination will be performed which consists of attention, verbal and visual memory, and executive functioning tests. Verbal memory will be assessed using the
Dutch version of the California Verbal Learning Test (VGLT). Non-verbal memory will be assessed with the recall of the Rey-Osterrieth Complex Figure Test. Executive functioning will be assessed using the Key Search and Rule Shift Cards from the Behavioural Assessment of the Dysexecutive Syndrome (BADS), letter fluency and categorical fluency, difference in time between part A and B of Trail Making Test, the interference score of the Stroop Color Word Test and the Stop Signal Task of the CANTAB. Attention will be assessed with the digit span forwards and backwards of the Wechsler Adult Intelligence Scale (WAIS). In addition, participants will fill out a validated questionnaire measuring cognitive symptoms (Cognitive Failures Questionnaire).

Baseline composite z-scores for the cognitive domains: attention, memory and executive functioning will be calculated by averaging the z-scores (raw individual test score at baseline minus the mean test score divided by the SD). Follow-up composite z-scores will be calculated for the cognitive domains: attention, memory and executive functioning by averaging the z-scores (raw individual test score at follow-up minus mean baseline test score divided by the SD of the baseline test score). These composite z-scores will be used in the further analysis.

**Measures of physical function**
Maximal exercise capacity (VO2max) or maximal oxygen consumption (ml/kg/min) is used as the measure of cardiorespiratory fitness. A symptom-limited ramp exercise test will be performed on a Jaeger cycle ergometer. During these tests, continuous ECG monitoring will be performed and the blood pressure will be measured every minute. Oxygen consumption (VO2) will be continuously measured using a metabolic measurement system, which is performed by a breath-by-breath gas analysis (Oxycon Pro, Jaeger). The testing protocol will be adjusted to the capabilities of the patient. Exercise will be terminated if participants are fatigued or earlier if they fulfil the
ACSM’s guidelines for ‘Indications for terminating Exercise Testing’. A cardiologist and pulmonologist will review all results of the exercise tests. In case of ECG-abnormalities, a cardiologist will examine the participant to exclude cardiac disease. The maximal value obtained will be considered as the VO2max.

The amount of self-reported physical activity will be measured using the Physical Activity Scale for the Elderly (PASE) questionnaire. This questionnaire has also been validated for the elderly patients in the Dutch population.

**Measures of secondary prevention**
Secondary prevention will be measured as the number of participants who achieve the composite endpoint of optimal medical therapy, defined as the combination of prescribed antithrombotic therapy (antiplatelet agents or oral anticoagulants) and achievement of both blood pressure (<140/90 mm Hg) and LDL-C (<100 mg/dl) targets. These cut-off points are based on current guidelines. Other endpoints are the individual components of the composite endpoint of optimal medical therapy, number of participants not smoking (self-reported), alcohol consumption (self-reported), body mass index and waist circumference.

**Recurrent vascular events**
All recurrent vascular events during the follow-up period of 2 years will be recorded. The trial is not sufficiently powered to determine the effect of the MoveIT programme in reducing recurrent TIA, stroke or cardiac events. Thus, it will be exploratory in this regard.

**Other**
Mental health and fatigue will be assessed using the Hospital Anxiety and Depression Scale (HADS) and the Fatigue Severity Scale.
**Covariates**

*Imaging*

At baseline, in all participants a non-contrast head CT scan will be performed as part of their routine stroke workup. In addition, in all participants without contraindications, a brain MRI will be performed after informed consent. The MR investigations will be performed on a 1.5-Tesla scanner. The protocol consists of sagittal T1-weighted (repetition time (TR)/echo time (TE): 1940/3.08 ms), sagittal fluid-attenuated inversion recovery (TR/TE 6000/358 ms), transversal T2-weighted (TR/TE 5000/96 ms), transversal T2-weighted gradient echo (TR/TE 800/26 ms) and diffusion-weighted imaging (TR/TE 4100/102 ms). Imaging will be used to evaluate markers of small vessel disease, brain atrophy and carotid calcifications.

*Apolipoprotein E*

APOE genotype, a genetic risk factor for Alzheimer disease, will be performed after DNA isolation from 10 ml EDTA blood by using the LightCycler APOE mutation detection method (Roche Diagnostics GmbH) and coded as APOE ε4 or no ε4.

*Other*

Pre-existent cognitive impairment will be assessed using the Informant Questionnaire for Cognitive Decline in Elderly (IQCODE). Premorbid intellectual functioning will be assessed using the Dutch version of the National Adult Reading Test (DART).

**Power calculation and sample size**

Global cognition, assessed with the MoCA test, was selected as the outcome variable to calculate sample size. Using estimates obtained from the literature and our previously performed pilot study, a sample size of 52 patients in each group is needed to reach a power of 80% to detect a difference in means in the MoCA score of 1.5 point, assuming a SD of 2.7 using a two-sample t-test with a 0.05 two-sided significance level. We
increased the sample size to 60 patients in each group to anticipate for potential dropouts.

**Analysis**
Baseline demographic and clinical characteristics of participants in the intervention and control groups will be compared using two-sample t-tests (continuous data) and chi-squared analysis (nominal data). Non-parametric methods will be used when assumptions of normality are violated. Primary analyses will be unadjusted, following the intention-to-treat principle. For the primary endpoint, the change in MoCA between the baseline and the 2-year follow-up will be calculated. Depending on the normality distribution, the change scores will be compared using either Wilcoxon rank-sum tests or two-sample t-tests with significance level of 0.05.

In the secondary analyses, we will assess the effect on our secondary outcome measures. We will calculate the change between the baseline and the 2 years continuous data, and this change score will be analysed using either Wilcoxon rank-sum tests or two-sample t-tests. We will perform logistic regression for the outcome measures with a dichotomous outcome, such as attainment of measures for secondary prevention using the data at the 2-year follow-up as the dependent variable and correcting for baseline using the baseline data as covariate.

A repeated-measures mixed design will be used to estimate the treatment effects (2 groups at 3 time points), using the variables measured at the baseline, and at the 1-year and 2-year follow-up that conform to the assumptions of normality. Level of significance will be <0.05. Data will be analysed using SPSS (V.20.0).

**Ethics and dissemination**
All minor and major amendments to the protocol will be approved
by the Ethics committee. A signed and dated informed consent form will be required from all participants. The risks and benefits of participation will be explained and all potential participants are free to decline to participate in the trial. All patient-level data accessed in this study will be stripped of personal identifiers. To guarantee the confidentiality of the participants, only the authors will have access to the data during the study.

We will disseminate the results of our study via presentations at international conferences and publications in peer-reviewed journals.

**Funding**

This work was supported by ZonMW (project number 60-82600-98-8338), Roomsch Catholijk Oude Armen Kantoor (project number 2010.101) and the ‘Innovatiefonds’ of the Sint Lucas Andreas Hospital 2010 (Motives MoveIT 2010).

**Ethics approval**

The study received ethical approval from the VU University Amsterdam Ethics Committee (2011/383).

**Trial registration**

The study is registered at the Nederlands Trial Register (NTR3884).
